<b>Index</b>	<b>41</b>

Sage supports solving clauses in Conjunctive Normal Form (see [Wikipedia article Conjunctive\\_normal\\_form](#)), i.e., SAT solving, via an interface inspired by the usual DIMACS format used in SAT solving [SG09]. For example, to express that:

```
x1 OR x2 OR (NOT x3)
```

should be true, we write:

```
(1, 2, -3)
```

**Warning**

Variable indices **must** start at one.

## SOLVERS

By default, Sage solves SAT instances as an Integer Linear Program (see `sage.numerical.mip`), but any SAT solver supporting the DIMACS input format is easily interfaced using the `sage.sat.solvers.dimacs.DIMACS` blueprint. Sage ships with pre-written interfaces for *RSat* [RS] and *Glucose* [GL]. Furthermore, Sage provides an interface to the *CryptoMiniSat* [CMS] SAT solver which can be used interchangeably with DIMACS-based solvers. For this last solver, the optional CryptoMiniSat package must be installed, this can be accomplished by typing the following in the shell:

```
sage -i cryptominisat sagelib
```

We now show how to solve a simple SAT problem.

```
(x1 OR x2 OR x3) AND (x1 OR x2 OR (NOT x3))
```

In Sage's notation:

```
sage: solver = SAT()
sage: solver.add_clause( ( 1, 2, 3) )
sage: solver.add_clause( ( 1, 2, -3) )
sage: solver()          # random
(None, True, True, False)
```

### Note

`add_clause()` creates new variables when necessary. When using CryptoMiniSat, it creates *all* variables up to the given index. Hence, adding a literal involving the variable 1000 creates up to 1000 internal variables.

DIMACS-base solvers can also be used to write DIMACS files:

```
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: solver.add_clause( ( 1, 2, 3) )
sage: solver.add_clause( ( 1, 2, -3) )
sage: _ = solver.write()
sage: for line in open(fn).readlines():
....:     print(line)
p cnf 3 2
1 2 3 0
1 2 -3 0
```

Alternatively, there is `sage.sat.solvers.dimacs.DIMACS.clauses()`:

```

sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS()
sage: solver.add_clause( ( 1, 2, 3) )
sage: solver.add_clause( ( 1, 2, -3) )
sage: solver.clauses(fn)
sage: for line in open(fn).readlines():
.....:     print(line)
p cnf 3 2
1 2 3 0
1 2 -3 0

```

These files can then be passed external SAT solvers.

## 1.1 Details on Specific Solvers

### 1.1.1 Abstract SAT Solver

All SAT solvers must inherit from this class.

#### Note

Our SAT solver interfaces are 1-based, i.e., literals start at 1. This is consistent with the popular DIMACS format for SAT solving but not with Python's 0-based convention. However, this also allows to construct clauses using simple integers.

#### AUTHORS:

- Martin Albrecht (2012): first version

`sage.sat.solvers.satsolver.SAT` (*solver=None, \*args, \*\*kws*)

Return a *SatSolver* instance.

Through this class, one can define and solve SAT problems.

#### INPUT:

- `solver` – string; select a solver. Admissible values are:
  - 'cryptominisat' – note that the pycryptosat package must be installed
  - 'picosat' – note that the pycosat package must be installed
  - 'glucose' – note that the glucose package must be installed
  - 'glucose-syrup' – note that the glucose package must be installed
  - 'LP' – use *SatLP* to solve the SAT instance
  - None – default; use CryptoMiniSat if available, else PicoSAT if available, and a LP solver otherwise

#### EXAMPLES:

```

sage: SAT(solver='LP')
↪needs sage.numerical.mip
an ILP-based SAT Solver

```

**class** sage.sat.solvers.satsolver.SatSolver

Bases: object

**add\_clause** (*lits*)

Add a new clause to set of clauses.

INPUT:

- *lits* – tuple of nonzero integers

#### Note

If any element *e* in *lits* has  $\text{abs}(e)$  greater than the number of variables generated so far, then new variables are created automatically.

EXAMPLES:

```
sage: from sage.sat.solvers.satsolver import SatSolver
sage: solver = SatSolver()
sage: solver.add_clause( (1, -2, 3) )
Traceback (most recent call last):
...
NotImplementedError
```

**clauses** (*filename=None*)

Return original clauses.

INPUT:

- *filename* – if not `None` clauses are written to *filename* in DIMACS format (default: `None`)

OUTPUT:

If *filename* is `None` then a list of *lits*, *is\_xor*, *rhs* tuples is returned, where *lits* is a tuple of literals, *is\_xor* is always `False` and *rhs* is always `None`.

If *filename* points to a writable file, then the list of original clauses is written to that file in DIMACS format.

EXAMPLES:

```
sage: from sage.sat.solvers.satsolver import SatSolver
sage: solver = SatSolver()
sage: solver.clauses()
Traceback (most recent call last):
...
NotImplementedError
```

**conflict\_clause** ()

Return conflict clause if this instance is UNSAT and the last call used assumptions.

EXAMPLES:

```
sage: from sage.sat.solvers.satsolver import SatSolver
sage: solver = SatSolver()
sage: solver.conflict_clause()
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
NotImplementedError
```

**learnt\_clauses** (*unitary\_only=False*)

Return learnt clauses.

INPUT:

- `unitary_only` – return only unitary learnt clauses (default: `False`)

EXAMPLES:

```
sage: from sage.sat.solvers.satsolver import SatSolver
sage: solver = SatSolver()
sage: solver.learnt_clauses()
Traceback (most recent call last):
...
NotImplementedError

sage: solver.learnt_clauses(unitary_only=True)
Traceback (most recent call last):
...
NotImplementedError
```

**nvars** ()

Return the number of variables.

EXAMPLES:

```
sage: from sage.sat.solvers.satsolver import SatSolver
sage: solver = SatSolver()
sage: solver.nvars()
Traceback (most recent call last):
...
NotImplementedError
```

**read** (*filename*)

Reads DIMAC files.

Reads in DIMAC formatted lines (lazily) from a file or file object and adds the corresponding clauses into this solver instance. Note that the DIMACS format is not well specified, see <http://people.sc.fsu.edu/~jburkardt/data/cnf/cnf.html>, <http://www.satcompetition.org/2009/format-benchmarks2009.html>, and [http://elis.dvo.ru/~lab\\_11/glpk-doc/cnfsat.pdf](http://elis.dvo.ru/~lab_11/glpk-doc/cnfsat.pdf).

The differences were summarized in the discussion on the issue [Issue #16924](#). This method assumes the following DIMACS format:

- Any line starting with “c” is a comment
- Any line starting with “p” is a header
- Any variable 1-n can be used
- Every line containing a clause must end with a “0”

The format is extended to allow lines starting with “x” defining `xor` clauses, with the notation introduced in [cryptominisat](https://www.msoos.org/xor-clauses/), see <https://www.msoos.org/xor-clauses/>

INPUT:

- `filename` – the name of a file as a string or a file object

EXAMPLES:

```
sage: from io import StringIO
sage: file_object = StringIO("c A sample .cnf file.\nnp cnf 3 2\n1 -3 0\n2 3 -
↪1 0 ")
sage: from sage.sat.solvers.dimacs import DIMACS
sage: solver = DIMACS()
sage: solver.read(file_object)
sage: solver.clauses()
[[ (1, -3), False, None), ((2, 3, -1), False, None)]
```

With xor clauses:

```
sage: from io import StringIO
sage: file_object = StringIO("c A sample .cnf file with xor clauses.\nnp cnf 3_
↪3\n1 2 0\n3 0\nx1 2 3 0")
sage: from sage.sat.solvers.cryptominisat import CryptoMiniSat #_
↪optional - pycryptosat
sage: solver = CryptoMiniSat() #_
↪optional - pycryptosat
sage: solver.read(file_object) #_
↪optional - pycryptosat
sage: solver.clauses() #_
↪optional - pycryptosat
[[ (1, 2), False, None), ((3,), False, None), ((1, 2, 3), True, True)]
sage: solver() #_
↪optional - pycryptosat
(None, True, True, True)
```

**var** (*decision=None*)

Return a *new* variable.

INPUT:

- *decision* – is this variable a decision variable?

EXAMPLES:

```
sage: from sage.sat.solvers.satsolver import SatSolver
sage: solver = SatSolver()
sage: solver.var()
Traceback (most recent call last):
...
NotImplementedError
```

## 1.1.2 SAT-Solvers via DIMACS Files

Sage supports calling SAT solvers using the popular DIMACS format. This module implements infrastructure to make it easy to add new such interfaces and some example interfaces.

Currently, interfaces to **RSat** and **Glucose** are included by default.

### Note

Our SAT solver interfaces are 1-based, i.e., literals start at 1. This is consistent with the popular DIMACS format for SAT solving but not with Python's 0-based convention. However, this also allows to construct clauses using simple

integers.

**AUTHORS:**

- Martin Albrecht (2012): first version
- Sébastien Labbé (2018): adding Glucose SAT solver
- Sébastien Labbé (2023): adding Kissat SAT solver

**Classes and Methods**

**class** `sage.sat.solvers.dimacs.DIMACS` (*command=None, filename=None, verbosity=0, \*\*kwds*)

Bases: `SatSolver`

Generic DIMACS Solver.

**Note**

Usually, users will not have to use this class directly but some class which inherits from this class.

**\_\_init\_\_** (*command=None, filename=None, verbosity=0, \*\*kwds*)

Construct a new generic DIMACS solver.

**INPUT:**

- `command` – a named format string with the command to run. The string must contain `{input}` and may contain `{output}` if the solvers writes the solution to an output file. For example “sat-solver `{input}`” is a valid command. If `None` then the class variable `command` is used. (default: `None`)
- `filename` – a filename to write clauses to in DIMACS format, must be writable. If `None` a temporary filename is chosen automatically. (default: `None`)
- `verbosity` – a verbosity level, where zero means silent and anything else means verbose output. (default: 0)
- `**kwds` – accepted for compatibility with other solvers; ignored

**\_\_call\_\_** (*assumptions=None*)

Solve this instance and return the parsed output.

**INPUT:**

- `assumptions` – ignored, accepted for compatibility with other solvers (default: `None`)

**OUTPUT:**

- If this instance is SAT: A tuple of length `nvars() + 1` where the `i`-th entry holds an assignment for the `i`-th variables (the 0-th entry is always `None`).
- If this instance is UNSAT: `False`

**EXAMPLES:**

When the problem is SAT:

```

sage: from sage.sat.solvers import RSat
sage: solver = RSat()
sage: solver.add_clause( (1, 2, 3) )
sage: solver.add_clause( (-1, ) )
sage: solver.add_clause( (-2, ) )
sage: solver() # optional - rsat
(None, False, False, True)

```

When the problem is UNSAT:

```

sage: solver = RSat()
sage: solver.add_clause((1,2))
sage: solver.add_clause((-1,2))
sage: solver.add_clause((1,-2))
sage: solver.add_clause((-1,-2))
sage: solver() # optional - rsat
False

```

With Glucose:

```

sage: from sage.sat.solvers.dimacs import Glucose
sage: solver = Glucose()
sage: solver.add_clause((1,2))
sage: solver.add_clause((-1,2))
sage: solver.add_clause((1,-2))
sage: solver() # optional - glucose
(None, True, True)
sage: solver.add_clause((-1,-2))
sage: solver() # optional - glucose
False

```

With GlucoseSyrup:

```

sage: from sage.sat.solvers.dimacs import GlucoseSyrup
sage: solver = GlucoseSyrup()
sage: solver.add_clause((1,2))
sage: solver.add_clause((-1,2))
sage: solver.add_clause((1,-2))
sage: solver() # optional - glucose
(None, True, True)
sage: solver.add_clause((-1,-2))
sage: solver() # optional - glucose
False

```

### **add\_clause** (*lits*)

Add a new clause to set of clauses.

INPUT:

- *lits* – tuple of nonzero integers

#### Note

If any element  $e$  in *lits* has  $\text{abs}(e)$  greater than the number of variables generated so far, then new variables are created automatically.

EXAMPLES:

```

sage: from sage.sat.solvers.dimacs import DIMACS
sage: solver = DIMACS()
sage: solver.var()
1
sage: solver.var(decision=True)
2
sage: solver.add_clause( (1, -2, 3) )
sage: solver
DIMACS Solver: ''

```

**clauses** (*filename=None*)

Return original clauses.

INPUT:

- *filename* – if not None clauses are written to *filename* in DIMACS format (default: None)

OUTPUT:

If *filename* is None then a list of lits, *is\_xor*, *rhs* tuples is returned, where *lits* is a tuple of literals, *is\_xor* is always False and *rhs* is always None.

If *filename* points to a writable file, then the list of original clauses is written to that file in DIMACS format.

EXAMPLES:

```

sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS()
sage: solver.add_clause( (1, 2, 3) )
sage: solver.clauses()
[(1, 2, 3), False, None]

sage: solver.add_clause( (1, 2, -3) )
sage: solver.clauses(fn)
sage: print(open(fn).read())
p cnf 3 2
1 2 3 0
1 2 -3 0

```

**command** = ''

**nvars** ()

Return the number of variables.

EXAMPLES:

```

sage: from sage.sat.solvers.dimacs import DIMACS
sage: solver = DIMACS()
sage: solver.var()
1
sage: solver.var(decision=True)
2
sage: solver.nvars()
2

```

**static render\_dimacs** (*clauses, filename, nlits*)

Produce DIMACS file *filename* from clauses.

INPUT:

- `clauses` – list of clauses, either in simple format as a list of literals or in extended format for Crypto-MiniSat: a tuple of literals, `is_xor` and `rhs`.
- `filename` – the file to write to
- `nlits` -- the number of literals appearing in ``clauses

EXAMPLES:

```
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS()
sage: solver.add_clause( (1, 2, -3) )
sage: DIMACS.render_dimacs(solver.clauses(), fn, solver.nvars())
sage: print(open(fn).read())
p cnf 3 1
1 2 -3 0
```

This is equivalent to:

```
sage: solver.clauses(fn)
sage: print(open(fn).read())
p cnf 3 1
1 2 -3 0
```

This function also accepts a “simple” format:

```
sage: DIMACS.render_dimacs([ (1,2), (1,2,-3) ], fn, 3)
sage: print(open(fn).read())
p cnf 3 2
1 2 0
1 2 -3 0
```

**var** (*decision=None*)

Return a *new* variable.

INPUT:

- `decision` – accepted for compatibility with other solvers; ignored

EXAMPLES:

```
sage: from sage.sat.solvers.dimacs import DIMACS
sage: solver = DIMACS()
sage: solver.var()
1
```

**write** (*filename=None*)

Write DIMACS file.

INPUT:

- `filename` – if `None` default filename specified at initialization is used for writing to (default: `None`)

EXAMPLES:

```
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
```

(continues on next page)

(continued from previous page)

```

sage: solver.add_clause( (1, -2, 3) )
sage: _ = solver.write()
sage: for line in open(fn).readlines():
....:     print(line)
p cnf 3 1
1 -2 3 0

sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS()
sage: solver.add_clause( (1, -2, 3) )
sage: _ = solver.write(fn)
sage: for line in open(fn).readlines():
....:     print(line)
p cnf 3 1
1 -2 3 0

```

**class** sage.sat.solvers.dimacs.Glucose (*command=None, filename=None, verbosity=0, \*\*kws*)

Bases: *DIMACS*

An instance of the Glucose solver.

For information on Glucose see: <http://www.labri.fr/perso/lisimon/glucose/>

EXAMPLES:

```

sage: from sage.sat.solvers import Glucose
sage: solver = Glucose()
sage: solver
DIMACS Solver: 'glucose -verb=0 -model {input}'

```

When the problem is SAT:

```

sage: from sage.sat.solvers import Glucose
sage: solver1 = Glucose()
sage: solver1.add_clause( (1, 2, 3) )
sage: solver1.add_clause( (-1,) )
sage: solver1.add_clause( (-2,) )
sage: solver1()                                     # optional - glucose
(None, False, False, True)

```

When the problem is UNSAT:

```

sage: solver2 = Glucose()
sage: solver2.add_clause((1,2))
sage: solver2.add_clause((-1,2))
sage: solver2.add_clause((1,-2))
sage: solver2.add_clause((-1,-2))
sage: solver2()                                     # optional - glucose
False

```

With one hundred variables:

```

sage: solver3 = Glucose()
sage: solver3.add_clause( (1, 2, 100) )
sage: solver3.add_clause( (-1,) )
sage: solver3.add_clause( (-2,) )

```

(continues on next page)

(continued from previous page)

```
sage: solver3()                                # optional - glucose
(None, False, False, ..., True)
```

```
command = 'glucose -verb=0 -model {input}'
```

```
class sage.sat.solvers.dimacs.GlucoseSyrup (command=None, filename=None, verbosity=0,
                                             **kwds)
```

Bases: *DIMACS*

An instance of the Glucose-syrup parallel solver.

For information on Glucose see: <http://www.labri.fr/perso/lsimon/glucose/>

EXAMPLES:

```
sage: from sage.sat.solvers import GlucoseSyrup
sage: solver = GlucoseSyrup()
sage: solver
DIMACS Solver: 'glucose-syrup -model -verb=0 {input}'
```

When the problem is SAT:

```
sage: solver1 = GlucoseSyrup()
sage: solver1.add_clause( (1, 2, 3) )
sage: solver1.add_clause( (-1,) )
sage: solver1.add_clause( (-2,) )
sage: solver1()                                # optional - glucose
(None, False, False, True)
```

When the problem is UNSAT:

```
sage: solver2 = GlucoseSyrup()
sage: solver2.add_clause((1,2))
sage: solver2.add_clause((-1,2))
sage: solver2.add_clause((1,-2))
sage: solver2.add_clause((-1,-2))
sage: solver2()                                # optional - glucose
False
```

With one hundred variables:

```
sage: solver3 = GlucoseSyrup()
sage: solver3.add_clause( (1, 2, 100) )
sage: solver3.add_clause( (-1,) )
sage: solver3.add_clause( (-2,) )
sage: solver3()                                # optional - glucose
(None, False, False, ..., True)
```

```
command = 'glucose-syrup -model -verb=0 {input}'
```

```
class sage.sat.solvers.dimacs.Kissat (command=None, filename=None, verbosity=0, **kwds)
```

Bases: *DIMACS*

An instance of the Kissat SAT solver.

For information on Kissat see: <http://fmv.jku.at/kissat/>

EXAMPLES:

```
sage: from sage.sat.solvers import Kissat
sage: solver = Kissat()
sage: solver
DIMACS Solver: 'kissat -q {input}'
```

When the problem is SAT:

```
sage: solver1 = Kissat()
sage: solver1.add_clause( (1, 2, 3) )
sage: solver1.add_clause( (-1,) )
sage: solver1.add_clause( (-2,) )
sage: solver1() # optional - kissat
(None, False, False, True)
```

When the problem is UNSAT:

```
sage: solver2 = Kissat()
sage: solver2.add_clause((1,2))
sage: solver2.add_clause((-1,2))
sage: solver2.add_clause((1,-2))
sage: solver2.add_clause((-1,-2))
sage: solver2() # optional - kissat
False
```

With one hundred variables:

```
sage: solver3 = Kissat()
sage: solver3.add_clause( (1, 2, 100) )
sage: solver3.add_clause( (-1,) )
sage: solver3.add_clause( (-2,) )
sage: solver3() # optional - kissat
(None, False, False, ..., True)
```

```
command = 'kissat -q {input}'
```

```
class sage.sat.solvers.dimacs.RSat (command=None, filename=None, verbosity=0, **kws)
```

Bases: *DIMACS*

An instance of the RSat solver.

For information on RSat see: <http://reasoning.cs.ucla.edu/rsat/>

EXAMPLES:

```
sage: from sage.sat.solvers import RSat
sage: solver = RSat()
sage: solver
DIMACS Solver: 'rsat {input} -v -s'
```

When the problem is SAT:

```
sage: from sage.sat.solvers import RSat
sage: solver = RSat()
sage: solver.add_clause( (1, 2, 3) )
sage: solver.add_clause( (-1,) )
sage: solver.add_clause( (-2,) )
sage: solver() # optional - rsat
(None, False, False, True)
```

When the problem is UNSAT:

```
sage: solver = RSat()
sage: solver.add_clause((1,2))
sage: solver.add_clause((-1,2))
sage: solver.add_clause((1,-2))
sage: solver.add_clause((-1,-2))
sage: solver() # optional - rsat
False
```

```
command = 'rsat {input} -v -s'
```

### 1.1.3 PicoSAT Solver

This solver relies on the `pycosat` Python bindings to PicoSAT.

The `pycosat` package should be installed on your Sage installation.

AUTHORS:

- Thierry Monteil (2018): initial version.

```
class sage.sat.solvers.picosat.PicoSAT(verbosity=0, prop_limit=0)
```

Bases: `SatSolver`

PicoSAT Solver.

INPUT:

- `verbosity` – integer between 0 and 2 (default: 0)
- `prop_limit` – integer (default: 0); the propagation limit

EXAMPLES:

```
sage: from sage.sat.solvers.picosat import PicoSAT
sage: solver = PicoSAT() # optional - pycosat
```

`add_clause` (*lits*)

Add a new clause to set of clauses.

INPUT:

- `lits` – tuple of nonzero integers

#### Note

If any element  $e$  in `lits` has  $\text{abs}(e)$  greater than the number of variables generated so far, then new variables are created automatically.

EXAMPLES:

```
sage: from sage.sat.solvers.picosat import PicoSAT
sage: solver = PicoSAT() # optional - pycosat
sage: solver.add_clause((1, -2, 3)) # optional - pycosat
```

**clauses** (*filename=None*)

Return original clauses.

INPUT:

- *filename* – (optional) if given, clauses are written to *filename* in DIMACS format

OUTPUT:

If *filename* is `None` then a list of `lits` is returned, where `lits` is a list of literals.

If *filename* points to a writable file, then the list of original clauses is written to that file in DIMACS format.

EXAMPLES:

```
sage: from sage.sat.solvers.picosat import PicoSAT
sage: solver = PicoSAT() # optional - pycosat
sage: solver.add_clause((1, 2, 3, 4, 5, 6, 7, 8, -9)) # optional - pycosat
sage: solver.clauses() # optional - pycosat
[[1, 2, 3, 4, 5, 6, 7, 8, -9]]
```

DIMACS format output:

```
sage: # optional - pycosat
sage: from sage.sat.solvers.picosat import PicoSAT
sage: solver = PicoSAT()
sage: solver.add_clause((1, 2, 4))
sage: solver.add_clause((1, 2, -4))
sage: fn = tmp_filename()
sage: solver.clauses(fn)
sage: print(open(fn).read())
p cnf 4 2
1 2 4 0
1 2 -4 0
```

**nvars** ()

Return the number of variables.

Note that for compatibility with DIMACS convention, the number of variables corresponds to the maximal index of the variables used.

EXAMPLES:

```
sage: from sage.sat.solvers.picosat import PicoSAT
sage: solver = PicoSAT() # optional - pycosat
sage: solver.nvars() # optional - pycosat
0
```

If a variable with intermediate index is not used, it is still considered as a variable:

```
sage: solver.add_clause((1, -2, 4)) # optional - pycosat
sage: solver.nvars() # optional - pycosat
4
```

**var** (*decision=None*)

Return a *new* variable.

INPUT:

- *decision* – ignored; accepted for compatibility with other solvers

EXAMPLES:

```
sage: from sage.sat.solvers.picosat import PicoSAT
sage: solver = PicoSAT() # optional - pycosat
sage: solver.var() # optional - pycosat
1
sage: solver.add_clause((-1, 2, -4)) # optional - pycosat
sage: solver.var() # optional - pycosat
5
```

## 1.1.4 Solve SAT problems Integer Linear Programming

The class defined here is a `SatSolver` that solves its instance using `MixedIntegerLinearProgram`. Its performance can be expected to be slower than when using `CryptoMiniSat`.

**class** `sage.sat.solvers.sat_lp.SatLP` (*solver=None, verbose=0, \*, integrality\_tolerance=0.001*)

Bases: `SatSolver`

Initialize the instance.

INPUT:

- `solver` – (default: `None`) specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `verbose` – integer (default: 0); sets the level of verbosity of the LP solver. Set to 0 by default, which means quiet.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`

EXAMPLES:

```
sage: S=SAT(solver='LP'); S
an ILP-based SAT Solver
```

**add\_clause** (*lits*)

Add a new clause to set of clauses.

INPUT:

- `lits` – tuple of nonzero integers

### Note

If any element  $e$  in `lits` has  $\text{abs}(e)$  greater than the number of variables generated so far, then new variables are created automatically.

EXAMPLES:

```
sage: S=SAT(solver='LP'); S
an ILP-based SAT Solver
sage: for u,v in graphs.CycleGraph(6).edges(sort=False, labels=False):
....:     u,v = u+1,v+1
```

(continues on next page)

(continued from previous page)

```
.....: S.add_clause((u,v))
.....: S.add_clause((-u,-v))
```

**nvars()**

Return the number of variables.

## EXAMPLES:

```
sage: S=SAT(solver='LP'); S
an ILP-based SAT Solver
sage: S.var()
1
sage: S.var()
2
sage: S.nvars()
2
```

**var()**

Return a *new* variable.

## EXAMPLES:

```
sage: S=SAT(solver='LP'); S
an ILP-based SAT Solver
sage: S.var()
1
```

## 1.1.5 CryptoMiniSat Solver

This solver relies on Python bindings provided by upstream cryptominisat.

## AUTHORS:

- Thierry Monteil (2017): complete rewrite, using upstream Python bindings, works with cryptominisat 5.
- Martin Albrecht (2012): first version, as a cython interface, works with cryptominisat 2.

```
class sage.sat.solvers.cryptominisat.CryptoMiniSat (verbosity=0, confl_limit=None,
                                                    threads=None)
```

Bases: *SatSolver*

CryptoMiniSat Solver.

## INPUT:

- `verbosity` – integer between 0 and 15 (default: 0)
- `confl_limit` – integer (default: None); abort after this many conflicts. If set to None, never aborts.
- `threads` – integer (default: None); the number of thread to use. If set to None, the number of threads used corresponds to the number of cpus.

## EXAMPLES:

```
sage: from sage.sat.solvers.cryptominisat import CryptoMiniSat
sage: solver = CryptoMiniSat() # optional -c
↪ pycryptosat
```

**add\_clause** (*lits*)

Add a new clause to set of clauses.

INPUT:

- *lits* – tuple of nonzero integers

**Note**

If any element *e* in *lits* has `abs(e)` greater than the number of variables generated so far, then new variables are created automatically.

EXAMPLES:

```
sage: from sage.sat.solvers.cryptominisat import CryptoMiniSat
sage: solver = CryptoMiniSat() # optional -L
↳ pycryptosat
sage: solver.add_clause((1, -2, 3)) # optional -L
↳ pycryptosat
```

**add\_xor\_clause** (*lits*, *rhs=True*)

Add a new XOR clause to set of clauses.

INPUT:

- *lits* – tuple of positive integers
- *rhs* – boolean (default: True); whether this XOR clause should be evaluated to True or False

EXAMPLES:

```
sage: from sage.sat.solvers.cryptominisat import CryptoMiniSat
sage: solver = CryptoMiniSat() # optional -L
↳ pycryptosat
sage: solver.add_xor_clause((1, 2, 3), False) # optional -L
↳ pycryptosat
```

**clauses** (*filename=None*)

Return original clauses.

INPUT:

- *filename* – if not None clauses are written to *filename* in DIMACS format (default: None)

OUTPUT:

If *filename* is None then a list of *lits*, *is\_xor*, *rhs* tuples is returned, where *lits* is a tuple of literals, *is\_xor* is always False and *rhs* is always None.

If *filename* points to a writable file, then the list of original clauses is written to that file in DIMACS format.

EXAMPLES:

```
sage: # optional - pycryptosat
sage: from sage.sat.solvers import CryptoMiniSat
sage: solver = CryptoMiniSat()
sage: solver.add_clause((1, 2, 3, 4, 5, 6, 7, 8, -9))
sage: solver.add_xor_clause((1, 2, 3, 4, 5, 6, 7, 8, 9), rhs=True)
```

(continues on next page)

(continued from previous page)

```
sage: solver.clauses()
[[ (1, 2, 3, 4, 5, 6, 7, 8, -9), False, None),
  (1, 2, 3, 4, 5, 6, 7, 8, 9), True, True]
```

DIMACS format output:

```
sage: # optional - pycryptosat
sage: from sage.sat.solvers import CryptoMiniSat
sage: solver = CryptoMiniSat()
sage: solver.add_clause((1, 2, 4))
sage: solver.add_clause((1, 2, -4))
sage: fn = tmp_filename()
sage: solver.clauses(fn)
sage: print(open(fn).read())
p cnf 4 2
1 2 4 0
1 2 -4 0
```

Note that in cryptominisat, the DIMACS standard format is augmented with the following extension: having an `x` in front of a line makes that line an XOR clause:

```
sage: solver.add_xor_clause((1,2,3), rhs=True) # optional - pycryptosat
sage: solver.clauses(fn) # optional - pycryptosat
sage: print(open(fn).read()) # optional - pycryptosat
p cnf 4 3
1 2 4 0
1 2 -4 0
x1 2 3 0
```

Note that inverting an xor-clause is equivalent to inverting one of the variables:

```
sage: solver.add_xor_clause((1,2,5), rhs=False) # optional - pycryptosat
sage: solver.clauses(fn) # optional - pycryptosat
sage: print(open(fn).read()) # optional - pycryptosat
p cnf 5 4
1 2 4 0
1 2 -4 0
x1 2 3 0
x1 2 -5 0
```

**nvars()**

Return the number of variables.

Note that for compatibility with DIMACS convention, the number of variables corresponds to the maximal index of the variables used.

EXAMPLES:

```
sage: from sage.sat.solvers.cryptominisat import CryptoMiniSat
sage: solver = CryptoMiniSat() # optional -
↪pycryptosat
sage: solver.nvars() # optional -
↪pycryptosat
0
```

If a variable with intermediate index is not used, it is still considered as a variable:

```

sage: solver.add_clause((1,-2,4)) # optional -
↪ pycryptosat
sage: solver.nvars() # optional -
↪ pycryptosat
4

```

**var** (*decision=None*)

Return a *new* variable.

INPUT:

- *decision* – accepted for compatibility with other solvers; ignored

EXAMPLES:

```

sage: from sage.sat.solvers.cryptominisat import CryptoMiniSat
sage: solver = CryptoMiniSat() # optional -
↪ pycryptosat
sage: solver.var() # optional -
↪ pycryptosat
1

sage: solver.add_clause((-1,2,-4)) # optional -
↪ pycryptosat
sage: solver.var() # optional -
↪ pycryptosat
5

```

## CONVERTERS

Sage supports conversion from Boolean polynomials (also known as Algebraic Normal Form) to Conjunctive Normal Form:

```
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B)
sage: e.clauses_sparse(a*b + a + 1)
sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 3 2
-2 0
1 0
```

## 2.1 Details on Specific Converters

### 2.1.1 An ANF to CNF Converter using a Dense/Sparse Strategy

This converter is based on two converters. The first one, by Martin Albrecht, was based on [CB2007], this is the basis of the “dense” part of the converter. It was later improved by Mate Soos. The second one, by Michael Brickenstein, uses a reduced truth table based approach and forms the “sparse” part of the converter.

AUTHORS:

- Martin Albrecht - (2008-09) initial version of ‘anf2cnf.py’
- Michael Brickenstein - (2009) ‘cnf.py’ for PolyBoRi
- Mate Soos - (2010) improved version of ‘anf2cnf.py’
- Martin Albrecht - (2012) unified and added to Sage

## Classes and Methods

```
class sage.sat.converters.polybori.CNFEncoder (solver, ring, max_vars_sparse=6,
                                             use_xor_clauses=None, cutting_number=6,
                                             random_seed=16)
```

Bases: ANF2CNFConverter

ANF to CNF Converter using a Dense/Sparse Strategy. This converter distinguishes two classes of polynomials.

1. Sparse polynomials are those with at most `max_vars_sparse` variables. Those are converted using reduced truth-tables based on PolyBoRi's internal representation.
2. Polynomials with more variables are converted by introducing new variables for monomials and by converting these linearised polynomials.

Linearised polynomials are converted either by splitting XOR chains – into chunks of length `cutting_number` – or by constructing XOR clauses if the underlying solver supports it. This behaviour is disabled by passing `use_xor_clauses=False`.

```
__init__ (solver, ring, max_vars_sparse=6, use_xor_clauses=None, cutting_number=6, random_seed=16)
```

Construct ANF to CNF converter over `ring` passing clauses to `solver`.

INPUT:

- `solver` – a SAT-solver instance
- `ring` – a `sage.rings.polynomial.pbori.BooleanPolynomialRing`
- `max_vars_sparse` – maximum number of variables for direct conversion
- `use_xor_clauses` – use XOR clauses; if `None` use if `solver` supports it. (default: `None`)
- `cutting_number` – maximum length of XOR chains after splitting if XOR clauses are not supported (default: 6)
- `random_seed` – the direct conversion method uses randomness, this sets the seed (default: 16)

EXAMPLES:

We compare the sparse and the dense strategies, sparse first:

```
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B)
sage: e.clauses_sparse(a*b + a + 1)
sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 3 2
-2 0
1 0
sage: e.phi
[None, a, b, c]
```

Now, we convert using the dense strategy:

```
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
```

(continues on next page)

(continued from previous page)

```

sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B)
sage: e.clauses_dense(a*b + a + 1)
sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 4 5
1 -4 0
2 -4 0
4 -1 -2 0
-4 -1 0
4 1 0
sage: e.phi
[None, a, b, c, a*b]

```

**Note**

This constructor generates SAT variables for each Boolean polynomial variable.

**\_\_call\_\_**(*F*)

Encode the boolean polynomials in *F*.

INPUT:

- *F* – an iterable of `sage.rings.polynomial.pbori.BooleanPolynomial`

OUTPUT: an inverse map int -> variable

EXAMPLES:

```

sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B, max_vars_sparse=2)
sage: e([a*b + a + 1, a*b + a + c])
[None, a, b, c, a*b]
sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 4 9
-2 0
1 0
1 -4 0
2 -4 0
4 -1 -2 0
-4 -1 -3 0
4 1 -3 0
4 -1 3 0
-4 1 3 0
sage: e.phi
[None, a, b, c, a*b]

```

**clauses**(*f*)

Convert *f* using the sparse strategy if `f.nvariables()` is at most `max_vars_sparse` and the dense

strategy otherwise.

INPUT:

- `f` – a `sage.rings.polynomial.pbori.BooleanPolynomial`

EXAMPLES:

```
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B, max_vars_sparse=2)
sage: e.clauses(a*b + a + 1)
sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 3 2
-2 0
1 0
sage: e.phi
[None, a, b, c]

sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B, max_vars_sparse=2)
sage: e.clauses(a*b + a + c)
sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 4 7
1 -4 0
2 -4 0
4 -1 -2 0
-4 -1 -3 0
4 1 -3 0
4 -1 3 0
-4 1 3 0

sage: e.phi
[None, a, b, c, a*b]
```

### `clauses_dense(f)`

Convert `f` using the dense strategy.

INPUT:

- `f` – a `sage.rings.polynomial.pbori.BooleanPolynomial`

EXAMPLES:

```
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B)
sage: e.clauses_dense(a*b + a + 1)
```

(continues on next page)

(continued from previous page)

```

sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 4 5
1 -4 0
2 -4 0
4 -1 -2 0
-4 -1 0
4 1 0
sage: e.phi
[None, a, b, c, a*b]

```

**clauses\_sparse**(*f*)

Convert *f* using the sparse strategy.

INPUT:

- *f* – a `sage.rings.polynomial.pbori.BooleanPolynomial`

EXAMPLES:

```

sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B)
sage: e.clauses_sparse(a*b + a + 1)
sage: _ = solver.write()
sage: print(open(fn).read())
p cnf 3 2
-2 0
1 0
sage: e.phi
[None, a, b, c]

```

**monomial**(*m*)

Return SAT variable for *m*.

INPUT:

- *m* – a monomial

OUTPUT: an index for a SAT variable corresponding to *m*

EXAMPLES:

```

sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B)
sage: e.clauses_dense(a*b + a + 1)
sage: e.phi
[None, a, b, c, a*b]

```

If `monomial` is called on a new monomial, a new variable is created:

```
sage: e.monomial(a*b*c)
5
sage: e.phi
[None, a, b, c, a*b, a*b*c]
```

If monomial is called on a monomial that was queried before, the index of the old variable is returned and no new variable is created:

```
sage: e.monomial(a*b)
4
sage: e.phi
[None, a, b, c, a*b, a*b*c]
```

### Note

For correctness, this function is cached.

**permutations** = Cached version of <function CNFEncoder.permutations>

### property phi

Map SAT variables to polynomial variables.

EXAMPLES:

```
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: ce = CNFEncoder(DIMACS(), B)
sage: ce.var()
4
sage: ce.phi
[None, a, b, c, None]
```

### split\_xor (monomial\_list, equal\_zero)

Split XOR chains into subchains.

INPUT:

- monomial\_list – list of monomials
- equal\_zero – is the constant coefficient zero?

EXAMPLES:

```
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: B.<a,b,c,d,e,f> = BooleanPolynomialRing()
sage: ce = CNFEncoder(DIMACS(), B, cutting_number=3)
sage: ce.split_xor([1,2,3,4,5,6], False)
[[[1, 7], False], [[7, 2, 8], True], [[8, 3, 9], True], [[9, 4, 10], True],
↪ [[10, 5, 11], True], [[11, 6], True]]

sage: ce = CNFEncoder(DIMACS(), B, cutting_number=4)
sage: ce.split_xor([1,2,3,4,5,6], False)
[[[1, 2, 7], False], [[7, 3, 4, 8], True], [[8, 5, 6], True]]
```

(continues on next page)

(continued from previous page)

```
sage: ce = CNFEncoder(DIMACS(), B, cutting_number=5)
sage: ce.split_xor([1,2,3,4,5,6], False)
[[[1, 2, 3, 7], False], [[7, 4, 5, 6], True]]
```

**to\_polynomial**(*c*)

Convert clause to `sage.rings.polynomial.pbori.BooleanPolynomial`.

INPUT:

- *c* – a clause

EXAMPLES:

```
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: fn = tmp_filename()
sage: solver = DIMACS(filename=fn)
sage: e = CNFEncoder(solver, B, max_vars_sparse=2)
sage: _ = e([a*b + a + 1, a*b + a + c])
sage: e.to_polynomial( (1,-2,3) )
a*b*c + a*b + b*c + b
```

**var**(*m=None, decision=None*)

Return a *new* variable.

This is a thin wrapper around the SAT-solvers function where we keep track of which SAT variable corresponds to which monomial.

INPUT:

- *m* – something the new variables maps to, usually a monomial
- *decision* – is this variable a decision variable?

EXAMPLES:

```
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: ce = CNFEncoder(DIMACS(), B)
sage: ce.var()
4
```

**zero\_blocks**(*f*)

Divide the zero set of *f* into blocks.

EXAMPLES:

```
sage: B.<a,b,c> = BooleanPolynomialRing()
sage: from sage.sat.converters.polybori import CNFEncoder
sage: from sage.sat.solvers.dimacs import DIMACS
sage: e = CNFEncoder(DIMACS(), B)
sage: sorted(sorted(d.items()) for d in e.zero_blocks(a*b*c))
[[[c, 0]], [[b, 0]], [[a, 0]]]
```

**Note**

This function is randomised.

## HIGHLEVEL INTERFACES

Sage provides various highlevel functions which make working with Boolean polynomials easier. We construct a very small-scale AES system of equations and pass it to a SAT solver:

```
sage: sr = mq.SR(1,1,1,4,gf2=True,polybori=True)
sage: while True:
.....:     try:
.....:         F,s = sr.polynomial_system()
.....:         break
.....:     except ZeroDivisionError:
.....:         pass
sage: from sage.sat.boolean_polynomials import solve as solve_sat # optional -
↳pycryptosat
sage: s = solve_sat(F) # optional -
↳pycryptosat
sage: F.subs(s[0]) # optional -
↳pycryptosat
Polynomial Sequence with 36 Polynomials in 0 Variables
```

### 3.1 Details on Specific Highlevel Interfaces

#### 3.1.1 SAT Functions for Boolean Polynomials

These highlevel functions support solving and learning from Boolean polynomial systems. In this context, “learning” means the construction of new polynomials in the ideal spanned by the original polynomials.

AUTHOR:

- Martin Albrecht (2012): initial version

#### Functions

```
sage.sat.boolean_polynomials.learn(F, converter=None, solver=None, max_learnt_length=3,
interreduction=False, **kwds)
```

Learn new polynomials by running SAT-solver `solver` on SAT-instance produced by `converter` from `F`.

INPUT:

- `F` – a sequence of Boolean polynomials
- `converter` – an ANF to CNF converter class or object. If `converter` is `None` then `sage.sat.converters.polybori.CNFEncoder` is used to construct a new converter. (default: `None`)

- `solver` – a SAT-solver class or object. If `solver` is `None` then `sage.sat.solvers.cryptominisat.CryptoMiniSat` is used to construct a new converter. (default: `None`)
- `max_learnt_length` – only clauses of length  $\leq$  `max_learnt_length` are considered and converted to polynomials. (default: 3)
- `interreduction` – inter-reduce the resulting polynomials (default: `False`)

**Note**

More parameters can be passed to the converter and the solver by prefixing them with `c_` and `s_` respectively. For example, to increase CryptoMiniSat's verbosity level, pass `s_verbosity=1`.

OUTPUT: a sequence of Boolean polynomials

EXAMPLES:

```
sage: from sage.sat.boolean_polynomials import learn as learn_sat
```

We construct a simple system and solve it:

```
sage: set_random_seed(2300)
sage: sr = mq.SR(1, 2, 2, 4, gf2=True, polybori=True)
sage: F, s = sr.polynomial_system()
sage: H = learn_sat(F)
sage: H[-1]
k033 + 1
```

`sage.sat.boolean_polynomials.solve` ( $F$ , `converter=None`, `solver=None`, `n=1`, `target_variables=None`, `**kws`)

Solve system of Boolean polynomials  $F$  by solving the SAT-problem – produced by `converter` – using `solver`.

INPUT:

- $F$  – a sequence of Boolean polynomials
- $n$  – number of solutions to return. If  $n$  is `+infinity` then all solutions are returned. If  $n$  is `<infinity` then  $n$  solutions are returned if  $F$  has at least  $n$  solutions. Otherwise, all solutions of  $F$  are returned. (default: 1)
- `converter` – an ANF to CNF converter class or object. If `converter` is `None` then `sage.sat.converters.polybori.CNFEncoder` is used to construct a new converter. (default: `None`)
- `solver` – a SAT-solver class or object. If `solver` is `None` then `sage.sat.solvers.cryptominisat.CryptoMiniSat` is used to construct a new converter. (default: `None`)
- `target_variables` – list of variables. The elements of the list are used to exclude a particular combination of variable assignments of a solution from any further solution. Furthermore `target_variables` denotes which variable-value pairs appear in the solutions. If `target_variables` is `None` all variables appearing in the polynomials of  $F$  are used to construct exclusion clauses. (default: `None`)
- `**kws` – parameters can be passed to the converter and the solver by prefixing them with `c_` and `s_` respectively. For example, to increase CryptoMiniSat's verbosity level, pass `s_verbosity=1`.

OUTPUT:

A list of dictionaries, each of which contains a variable assignment solving  $F$ .

EXAMPLES:

We construct a very small-scale AES system of equations:

```

sage: sr = mq.SR(1, 1, 1, 4, gf2=True, polybori=True)
sage: while True: # workaround (see :issue:`31891`)
.....:     try:
.....:         F, s = sr.polynomial_system()
.....:         break
.....:     except ZeroDivisionError:
.....:         pass

```

and pass it to a SAT solver:

```

sage: from sage.sat.boolean_polynomials import solve as solve_sat
sage: s = solve_sat(F)
sage: F.subs(s[0])
Polynomial Sequence with 36 Polynomials in 0 Variables

```

This time we pass a few options through to the converter and the solver:

```

sage: s = solve_sat(F, c_max_vars_sparse=4, c_cutting_number=8)
sage: F.subs(s[0])
Polynomial Sequence with 36 Polynomials in 0 Variables

```

We construct a very simple system with three solutions and ask for a specific number of solutions:

```

sage: B.<a,b> = BooleanPolynomialRing()
sage: f = a*b
sage: l = solve_sat([f],n=1)
sage: len(l) == 1, f.subs(l[0])
(True, 0)

sage: l = solve_sat([a*b],n=2)
sage: len(l) == 2, f.subs(l[0]), f.subs(l[1])
(True, 0, 0)

sage: sorted((d[a], d[b]) for d in solve_sat([a*b], n=3))
[(0, 0), (0, 1), (1, 0)]
sage: sorted((d[a], d[b]) for d in solve_sat([a*b], n=4))
[(0, 0), (0, 1), (1, 0)]
sage: sorted((d[a], d[b]) for d in solve_sat([a*b], n=infinity))
[(0, 0), (0, 1), (1, 0)]

```

In the next example we see how the `target_variables` parameter works:

```

sage: from sage.sat.boolean_polynomials import solve as solve_sat
sage: R.<a,b,c,d> = BooleanPolynomialRing()
sage: F = [a + b, a + c + d]

```

First the normal use case:

```

sage: sorted((D[a], D[b], D[c], D[d])
.....:         for D in solve_sat(F, n=infinity))
[(0, 0, 0, 0), (0, 0, 1, 1), (1, 1, 0, 1), (1, 1, 1, 0)]

```

Now we are only interested in the solutions of the variables `a` and `b`:

```

sage: solve_sat(F, n=infinity, target_variables=[a,b])
[{b: 0, a: 0}, {b: 1, a: 1}]

```

Here, we generate and solve the cubic equations of the AES SBox (see [Issue #26676](#)):

```
sage: # long time
sage: from sage.rings.polynomial.multi_polynomial_sequence import_
↳PolynomialSequence
sage: from sage.sat.boolean_polynomials import solve as solve_sat
sage: sr = sage.crypto.mq.SR(1, 4, 4, 8,
....:                        allow_zero_inversions=True)
sage: sb = sr.sbox()
sage: eqs = sb.polynomials(degree=3)
sage: eqs = PolynomialSequence(eqs)
sage: variables = map(str, eqs.variables())
sage: variables = ",".join(variables)
sage: R = BooleanPolynomialRing(16, variables)
sage: eqs = [R(eq) for eq in eqs]
sage: sls_aes = solve_sat(eqs, n=infinity)
sage: len(sls_aes)
256
```

**Note**

Although supported, passing converter and solver objects instead of classes is discouraged because these objects are stateful.
